

Autonomous regional Z-M latch exposes an entry-exit timing conflict

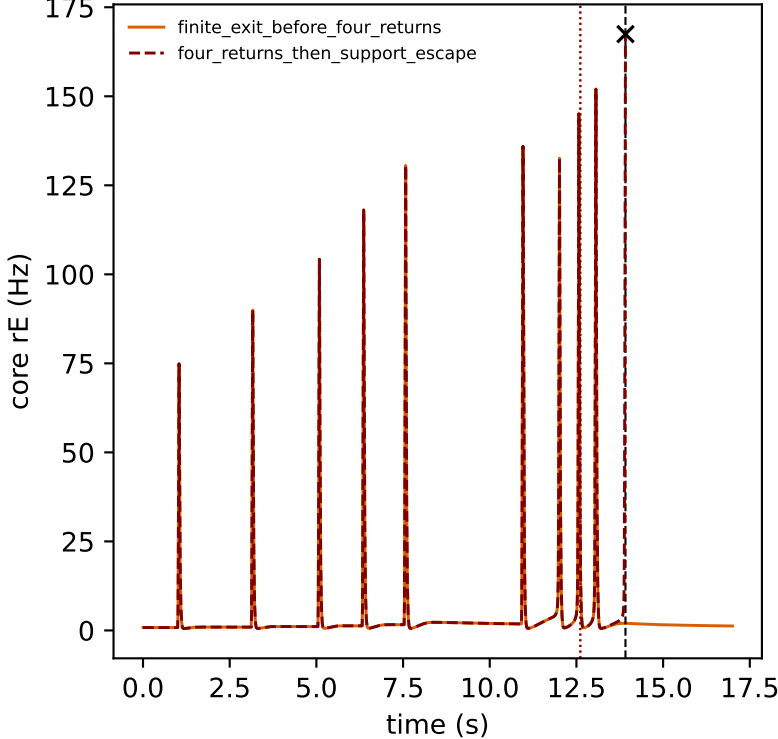

A Fixed background events return to interictal

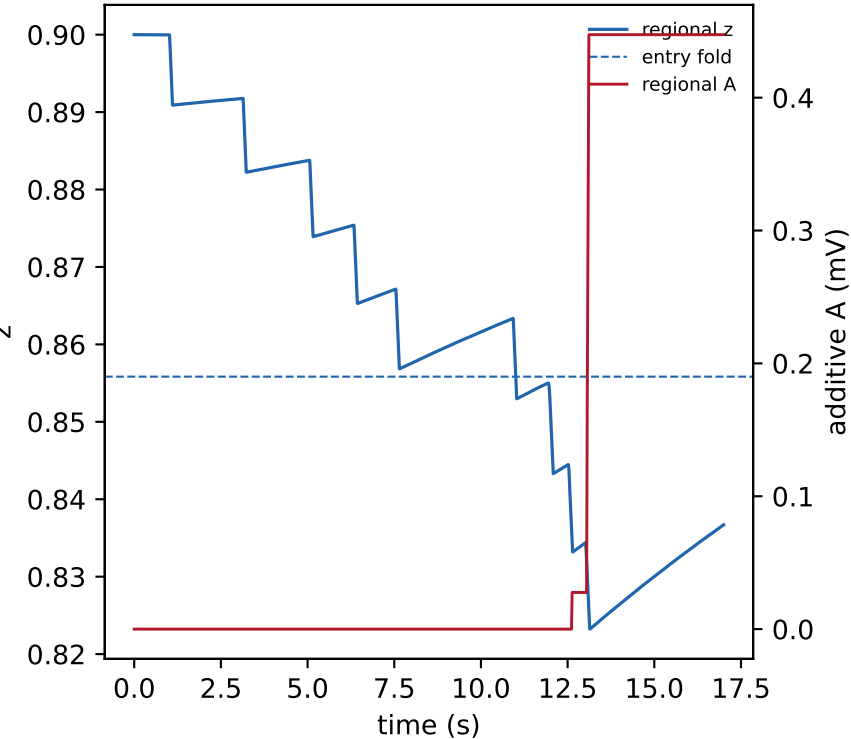

B Z-only crosses the fold but keeps accelerating

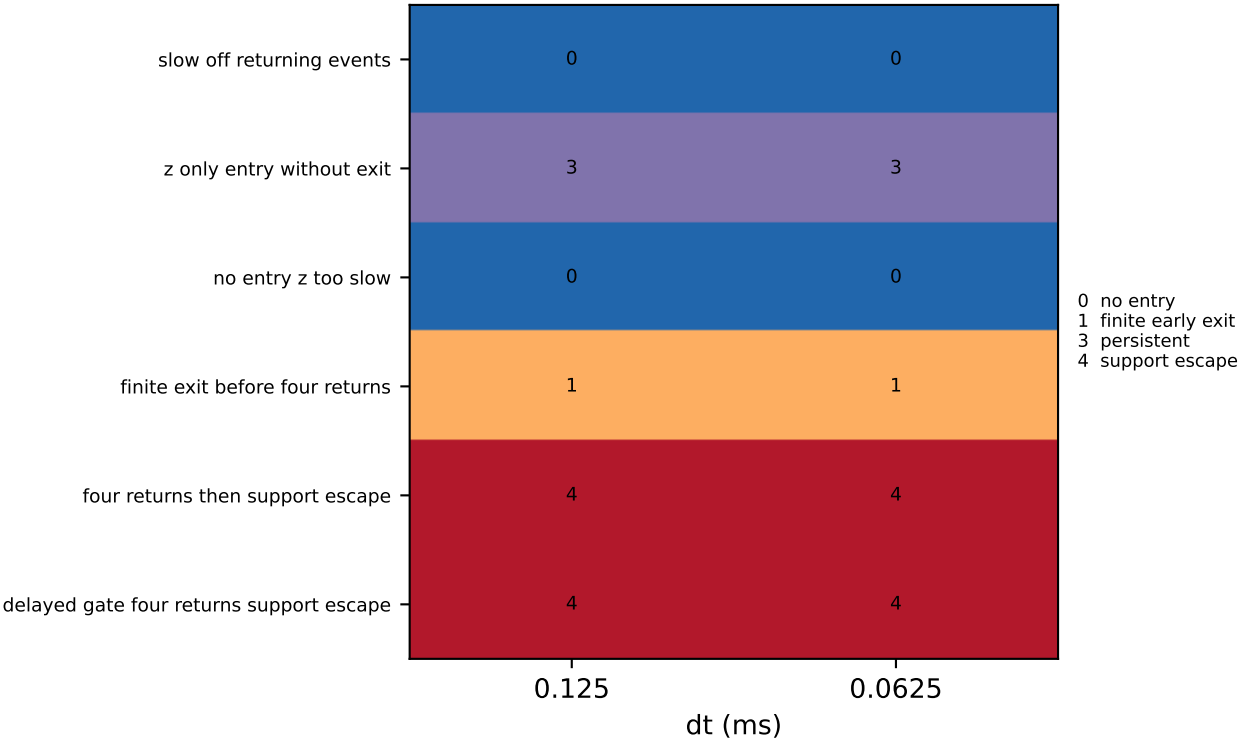

C Three-return exit vs four-return support escape

D Outer slow trajectory on measured boundaries

E Registered outcome matrix

F Mechanistic verdict

regional Z fold: PASS
bounded CCO target: PASS (frozen oracle)
bath stays low with fixed-resource mask: PASS

fast-M exit: 3 pulse-free returns, then low
slower-M arm: 4 returns, then support escape

No arm satisfies both ≥ 4 returns and finite exit.
The same Z-use law required for sparse-event entry
continues to drive z below the validated CCO window.

Registered-margin clean no-go for this additive latch;
do not resume downstream workflows yet.
